1.0 ABSTRACT

Agriculture is a cornerstone of global food security, yet farmers often struggle with unpredictable crop yields due to fluctuating environmental conditions. To address this challenge, our project leverages advanced machine learning techniques to predict the most suitable crops based on key environmental and soil parameters. We employed three state-of-the-art gradient-boosting algorithms which are CatBoost, LightGBM, and XGBoost, due to their proven effectiveness in handling structured data, robustness against overfitting, and superior performance in classification tasks. Through hyperparameter optimization using RandomizedSearchCV with 3-fold cross-validation which tested 20 parameter combinations per algorithm, we identified optimal configurations including learning rates (0.01-0.1), tree depths (4-10), and regularization parameters that maximized predictive performance..

These models were trained on a comprehensive dataset containing critical agricultural variables, including nitrogen (N), phosphorus (P), and potassium (K) ratios, temperature, humidity, soil pH levels, and rainfall. The primary challenge was ensuring the models' generalizability across diverse farming conditions, which we addressed through rigorous feature engineering, cross-validation, and hyperparameter tuning. Key tuned parameters included CatBoost's border_count (32-254) and bagging_temperature (0-4), LightGBM's num_leaves (20-70) and feature_fraction (0.6-0.8), and XGBoost's subsample (0.6-1.0) and colsample_bytree (0.6-1.0) ratios.

Our results were highly promising, CatBoost reached 99.32%, LightGBM 98.86%, and XGBoost 99.09% classification accuracy. The confusion matrices and classification reports further confirmed minimal misclassifications, indicating that these models can effectively guide farmers in selecting optimal crops for their land. This project underscores the transformative potential of machine learning in precision agriculture, enabling data-driven decisions that enhance productivity, sustainability, and resource efficiency.

2.0 INTRODUCTION

Agriculture is the backbone of economies worldwide, yet it remains vulnerable to environmental variability, resource mismanagement, and climate change. Traditional farming practices often rely on historical trends, manual observations, and intuition, which can lead to suboptimal crop choices, financial losses, and environmental degradation. To mitigate these challenges, modern agriculture increasingly adopts data-driven approaches, where machine learning (ML) plays a pivotal role in optimizing decision-making. Our implementation leverages advanced hyperparameter tuning techniques to maximize model accuracy and reliability for real-world agricultural conditions.

Problem Statement

Farmers face difficulties in:

- Predicting crop suitability due to dynamic soil and weather conditions.
- Allocating resources efficiently without precise yield forecasts.
- Minimizing risks associated with poor harvests, pests, and climate anomalies.

To address these issues, we developed an AI-powered crop recommendation system that analyzes environmental and soil data to predict the best crops for cultivation. Through systematic hyperparameter optimization of gradient boosting algorithms, we achieved more than 98% prediction accuracy, ensuring robust performance across diverse farming scenarios.

Dataset & Justification

We sourced our dataset from Kaggle:

- https://www.kaggle.com/datasets/atharvaingle/crop-recommendation-dataset

The dataset consisted of 2200 data that were gathered from India and was created by combining information from several sources, including rainfall, climate, and fertilizer usage data across India. It brings together some of the key factors that influence crop growth:

1. N - Nitrogen content in soil
2. P - Phosphorus content in soil
3. K - Potassium content in soil
4. Temperature - measured in degree celsius
5. Humidity - percentage of moisture in air
6. pH - Acidity or alkalinity in soil

7. Rainfall - total rainfall in millimeters(mm)

Each row in the dataset represents a unique set of these conditions, with the goal of predicting the crop that would thrive best under those circumstances.

Since the crop names are labels and not in numeric form, they need to be converted into a format that machine learning models can understand. To do this, the dataset uses One-Hot Encoding or Label Encoding, which turns the crop names into numerical values without losing their meaning. This step makes the data model-ready and helps improve the accuracy of the predictions.

This dataset was chosen because:

1. It covers critical growth-influencing factors recognized in agronomy.
2. It provides geographical diversity, ensuring model applicability across regions.
3. It aligns with Sustainable Development Goals (SDGs), particularly "Zero Hunger" and "Life on Land", by promoting sustainable farming.

Project Objectives

1. Develop a highly accurate ML model to recommend crops based on environmental inputs.
2. Compare performance of CatBoost, LightGBM, and XGBoost for agricultural applications.
3. Creating a model that can be an accessible tool for farmers and agronomists.

By achieving these goals, our project contributes to smart farming, where AI aids in maximizing yields, reducing waste, and fostering sustainability. The hyperparameter-tuned models demonstrate how precision agriculture can benefit from optimized machine learning pipelines.

3.0 METHODOLOGY/EXPERIMENTAL SETUP

3.1 LITERATURE REVIEW

In recent years, machine learning has played an increasingly important role in agriculture, especially in predicting suitable crops based on environmental and soil conditions. Among many algorithms, gradient boosting models like XGBoost, CatBoost, and LightGBM have shown excellent performance in this area.

XGBoost (Chen & Guestrin, 2016) is a highly efficient and scalable implementation of gradient boosting that uses regularization and tree pruning to reduce overfitting. It supports parallel computing, handles missing data, and has been widely adopted in both academic research and real-world applications, including crop classification and yield prediction.

A study by Rahman et al. (2020) applied machine learning for crop recommendation in Bangladesh and found that ensemble methods like XGBoost and LightGBM outperformed traditional models. Their research highlighted how environmental features such as soil nutrients, rainfall, and temperature can effectively be used to build predictive systems.

Building on these foundations, Mahesh & Soundrapandiyan (2024) conducted a detailed study comparing XGBoost, LightGBM, and CatBoost for crop yield prediction. Their results showed that all three models achieved high prediction accuracy, with CatBoost outperforming the others in terms of Mean Absolute Percentage Error (MAPE), demonstrating 99.1% accuracy. The paper also highlighted how gradient boosting models can handle both numerical and categorical data, and their ability to prevent overfitting through techniques like ordered boosting (in CatBoost).

In particular, Mahesh & Soundrapandiyan emphasized that:

- XGBoost offers robust performance and scalability for complex agricultural data.
- CatBoost is highly effective with categorical variables and avoids prediction shift issues.
- LightGBM is the fastest in training, making it ideal for large datasets.

All three algorithms showed superior performance over traditional models like Decision Trees, Support Vector Machines (SVM), and Neural Networks, especially when evaluated using multiple error metrics such as RMSE, R^2, and MAE.

3.2 JUSTIFICATION

Reason	Explanation
1.Better Accuracy	These models use a method called boosting, which means they build many decision trees, one after another, and each tree tries to fix the mistakes of the previous one. This helps them achieve much better accuracy compared to basic models like logistic regression, K-nearest neighbors, or support vector machines.
2. Works well with real world data	Real life data, especially in agriculture, often has some noise or outliers. Boosting models are less affected by these issues because of the way they learn in steps, making them more reliable in practice.
3. Easy to understand which features are important	All three models can show us which features (like rainfall, temperature, nitrogen level) were most important in making predictions. This is helpful because it gives us insights into why a certain crop is recommended.
4. Fast and efficient	i) LightGBM is designed to be very fast and uses less memory than most models. It is great for large datasets. ii) CatBoost is easy to use because it can handle categorical data (like names or labels) without needing much data cleaning. iii) XGBoost is very popular for competitions and real-world projects because it combines speed and accuracy with good generalization.
5. Can handle many crop types	Since this is a multiclass classification problem (we are predicting one crop out of 22 possible types), we needed models that can handle multiple classes easily. XGBoost, CatBoost, and LightGBM support this directly and are good at managing class imbalances too.

3.3 ALGORITHM IMPLEMENTATION

Before applying any machine learning model, we cleaned and prepared the dataset as follows:

- Feature Selection: We used features like Nitrogen (N), Phosphorus (P), Potassium (K), Temperature, Humidity, pH, and Rainfall.
- Label Encoding: Since the crop types are text labels (e.g: "rice", "wheat"), we used LabelEncoder from sklearn to convert them into numeric form.
- Train-Test Split: The dataset was split into 80% training and 20% testing using train_test_split to evaluate how well the models generalize to unseen data.

i) CatBoost Implementation

Code	Explanation

`import pandas as pd`
`import numpy as np`
`import matplotlib.pyplot as plt`
`import seaborn as sns`
`from catboost import CatBoostClassifier`
`from sklearn.model_selection import train_test_split`
`from sklearn.preprocessing import LabelEncoder`
`from sklearn.metrics import accuracy_score, classification_report, confusion_matrix`
	Imports the necessary libraries:
	
	i) pandas & numpy: for data handling
	
	ii) matplotlib & seaborn: for plotting results
	
	iii) CatBoostClassifier: the machine learning model
	
	iv) train_test_split, LabelEncoder, and metrics: for splitting data, encoding labels, and evaluating model performance

`label_encoder = LabelEncoder()` `df["label"] = label_encoder.fit_transform(df["label"])`	Converts the target crop names into numeric values. Machine learning models work with numbers, not text. Example: rice → 17, wheat → 21

`X = df.drop(columns=["label"])` `y = df["label"]`	X: contains the input features (N, P, K, temperature, humidity, pH, rainfall) y: contains the encoded crop label (the prediction target)
`catboost_model = CatBoostClassifier(iterations=500, learning_rate=0.05, depth=6, verbose=False)` `catboost_model.fit(X_train, y_train)`	Initializes a CatBoostClassifier with: i) 500 trees (iterations) ii) A learning rate of 0.05 iii) Maximum tree depth of 6
`y_pred = catboost_model.predict(X_test)`	Uses the trained model to predict crop types on the test data

`accuracy = accuracy_score(y_test, y_pred)`
`print(f"CatBoost Accuracy: {accuracy:.4f}")`
`print("\nClassification Report:\n", classification_report(y_test, y_pred))`
	Calculates accuracy score ,shows how many predictions were correct and prints the classification report (includes precision, recall, and F1-score for each crop)

ii) LightGBM

Code	**Explanation**
`train_data = lgb.Dataset(X_train, label=y_train)` `test_data = lgb.Dataset(X_test, label=y_test, reference=train_data)`	Converts pandas DataFrames into LightGBM's internal dataset format, which is optimized for training speed.
`params = {`	Configures the model:

`"objective": "multiclass",`
`"metric": "multi_logloss",`
`"boosting_type": "gbdt",`
`"learning_rate": 0.03,`
`"num_leaves": 20,`
`"max_depth": 6,`
`"min_data_in_leaf": 50,`
`"feature_fraction": 0.7,`
`"bagging_fraction": 0.7,`
`"num_class":`
`len(np.unique(y))`
`}`
	i) objective: This is a multi-class classification problem.
	
	ii) metric: Uses log loss to measure performance.
	
	iii) learning_rate, num_leaves, max_depth: Control how trees grow.
	
	iv) feature_fraction, bagging_fraction: Randomly sample features and data for better generalization.
	
	v) num_class: Total number of crop types to predict

`lightgbm_model =`
`lgb.train(params, train_data,`
`num_boost_round=500,`
`valid_sets=[test_data])`
	i) Trains the model using the given parameters and training data
	
	ii) Runs for 500 boosting rounds (trees)
	
	iii) Evaluates on the test set during training

iii) XGBoost

Code	**Explanation**

`xgboost_model =`
`xgb.XGBClassifier(n_estimators=500, learning_rate=0.05,`
`max_depth=6)`
`xgboost_model.fit(X_train, y_train)`
	-Creates an XGBoost classifier with the following settings:
	i) n_estimators=500: Builds 500 trees
	ii) learning_rate=0.05: Controls how quickly the model learns
	iii) max_depth=6: Limits how deep each tree can grow
	
	-Fits (trains) the model on the training data

iv)CatBoost + tuning

Code	**Explanation**

``python
param_dist = {
    'iterations': [250, 500, 750, 1000],
    'learning_rate': [0.01, 0.05, 0.1, 0.2],
    'depth': [4, 6, 8, 10],
    'l2_leaf_reg': [1, 3, 5, 7, 9],
    'border_count': [32, 64, 128, 254],
    'bagging_temperature': [0, 1, 2, 4],
    'random_strength': [1, 2, 3, 4]
}
``
	-Defines a list of possible values for each CatBoost hyperparameter to be explored by RandomizedSearchCV

``python
# Initialize CatBoostClassifier 	
cbc = CatBoostClassifier(verbose=0, thread_count=-1)
``
	-Initializes CatBoost without showing training output (verbose=0).
	
	-Uses all available CPU cores for faster training (thread_count=-1).

``python
# Setup RandomizedSearchCV 	
random_search = RandomizedSearchCV(
    cbc,
 	
param_distributions=param_dist,
    n_iter=20,
    scoring='accuracy',
    cv=3,
    verbose=1,
    random_state=42,
    n_jobs=-1
)
``
	-This will randomly try 20 different hyperparameter combinations from param_dist, each evaluated with 3 fold cross validation.

``python
# Fit model with hyperparameter tuning 	
print("Starting hyperparameter tuning...")
random_search.fit(X_train, y_train)
``
	-Starts the randomized search and trains the model 20 times to find the best hyperparameters.

``` # Best estimator best_model = random_search.best_estimator_ # Predictions with best model y_pred = best_model.predict(X_test) ```	-Extracts the best performing model from the search results. -Uses the best model to make predictions on the test set.

iv)LightGBM + tuning

Code	**Explanation**

``
# Define parameter grid for hyperparameter tuning 	
param_dist = {
'num_leaves': [20, 31, 50, 70],
'max_depth': [6, 8, 10, -1],
'learning_rate': [0.01, 0.03, 0.05, 0.1],
'min_data_in_leaf': [20, 50, 100],
'feature_fraction': [0.6, 0.7, 0.8],
'bagging_fraction': [0.6, 0.7, 0.8],
'bagging_freq': [0, 5, 10],
'lambda_l1': [0, 0.1, 0.5],
'lambda_l2': [0, 0.1, 0.5]
}
``
	These are the parameters that we put in LightGBM so that it will randomly try different combinations of:
	
	• num_leaves: Max number of leaves in trees
	
	• max_depth: Tree depth (-1 means no limit)
	
	• learning_rate: Step size at each boosting iteration
	
	• min_data_in_leaf: Controls overfitting by setting minimum samples in leaf
	• feature_fraction & bagging_fraction: Randomly sample features/rows for each iteration
	
	• bagging_freq: Frequency of bagging
	
	• lambda_l1, lambda_l2: L1 and L2 regularization

``` # Initialize the classifier lgb_clf = lgb.LGBMClassifier(objective='multiclass', metric='multi_logloss', ```	- objective='multiclass': Since we are predicting more than 2 crop types. -metric='multi_logloss': Common metric for multiclass classification.

`n_jobs=-1, verbose=-1)`	-n_jobs=-1: Use all CPU cores to speed up training. -verbose=-1: Hides training logs.

`# Set up RandomizedSearchCV`
`random_search = RandomizedSearchCV(`
`lgb_clf,`
 	
`param_distributions=param_dist,`
`n_iter=20,`
`scoring='accuracy',`
`cv=3,`
`verbose=1,`
`random_state=42,`
`n_jobs=-1`
`)`
	-Tries 20 random combinations of the parameters defined earlier.
	
	-Uses 3 fold cross validation for accuracy scoring.
	
	-n_jobs=-1: Parallel computation to speed up training.

iv)XGBoost + tuning

Code	Explanation

`# Define hyperparameter grid for tuning`
`param_dist = {`
`'n_estimators': [100, 200, 300, 500],`
`'max_depth': [3, 5, 6, 8, 10],`
`'learning_rate': [0.01, 0.05, 0.1],`
`'subsample': [0.6, 0.8, 1.0],`
`'colsample_bytree': [0.6, 0.8, 1.0],`
`'min_child_weight': [1, 3,`
	These are tuning ranges for important XGBoost hyperparameters:
	● n_estimators: Number of trees.
	● max_depth: Tree depth.
	● learning_rate: Step size.
	● subsample: Row sampling for each tree.
	● colsample_bytree: Feature sampling.
	● min_child_weight: Minimum samples per leaf.

5], 'reg_alpha': [0, 0.1, 0.5], 'reg_lambda': [1, 1.5, 2] }	• reg_alpha, reg_lambda: L1 and L2 regularization terms.
# Initialize XGBClassifier xgb_clf = xgb.XGBClassifier(objective='multi:softmax', num_class=len(np.unique(y)), use_label_encoder=False, n_jobs=-1)	-objective='multi:softmax': For multiclass classification. -num_class: Total number of crop categories. -use_label_encoder=False: Suppresses warnings from older versions. -n_jobs=-1: Use all CPU cores.
# Set up RandomizedSearchCV random_search = RandomizedSearchCV(lgb_clf, param_distributions=param_dist, n_iter=20, scoring='accuracy', cv=3, verbose=1, random_state=42, n_jobs=-1)	-Tries 20 random combinations of the parameters defined earlier. -Uses 3 fold cross validation for accuracy scoring. -n_jobs=-1: Parallel computation to speed up training.

4.0 RESULTS & DISCUSSION

4.1 RESULTS

i) Catboost

a. Confusion Matrix

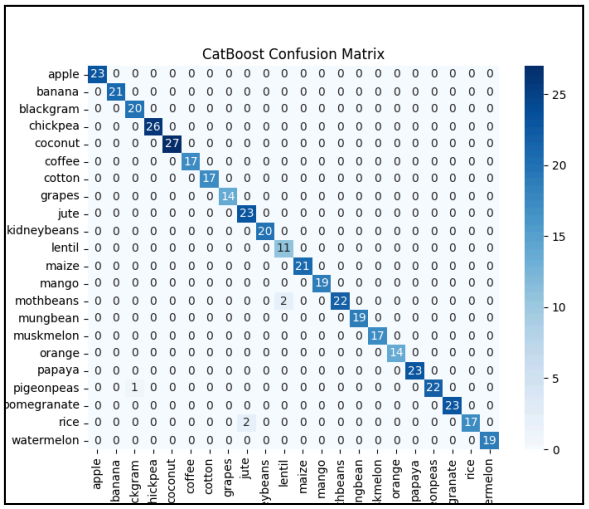

Figure 1: Confusion Matrix for the CatBoost algorithm

Observation gained from the confusion matrix:

- Diagonal Values (Correct Classifications): The highest values for each category are on the diagonal, indicating that the model is correctly classifying most instances.
- Misclassification Patterns: The values that are not in the diagonal show where the model is making errors. There are only 5 values that are outside of the diagonal, this shows that this model performs really well.

b. Feature Importance Graph

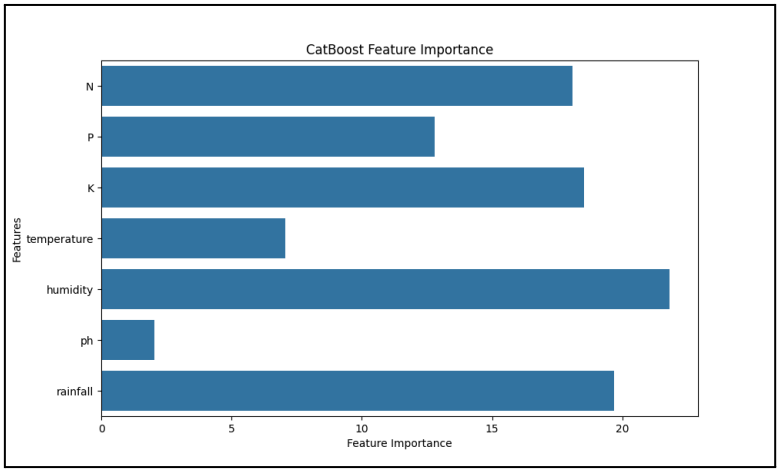

Figure 2: Feature Importance Graph for the CatBoost algorithm

- Features like humidity, rainfall, K, and N have higher importance scores, meaning they contribute more significantly to the model's predictions.
- Features like ph and temperature are less important, with lower importance scores.
- The importance scores help identify which features are most influential in predicting the target variable.

c. Accuracy & Classification Report

- CatBoost accuracy (0.9886):
  - The overall accuracy of the model is approximately 98.86%, meaning it correctly predicted the class for about 98.86% of the samples.
- Classification Report:
  - Shows the precision, recall, F1-score, and support for each class.
  - Macro average:
    - Precision: 0.99
    - Recall: 0.99
    - F1-score: 0.99
    - Support: 440 samples
    - All metrics show the score of 0.99, indicating high balanced performance across classes.
  - Weighted Average:

- Precision: 0.99
- Recall: 0.99
- F1-score: 0.99
- Support: 440 samples
- Similar to macro average, it shows high balanced performance across classes.

- The model performs exceptionally well, achieving near-perfect precision, recall, and F1-score across the classes

ii) CatBoost + Hyperparameter Tuning

a. Confusion Matrix

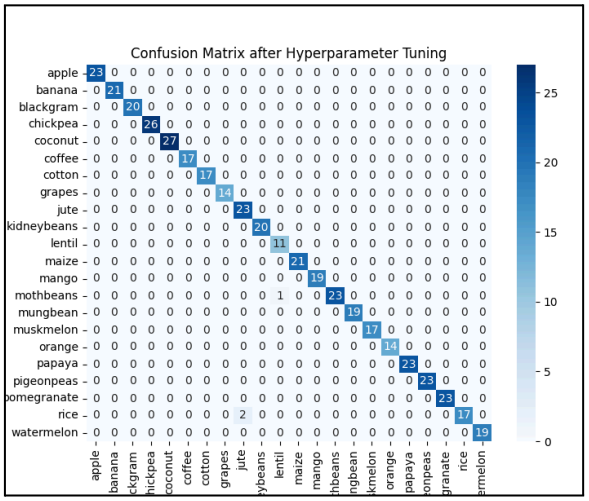

Figure 3: Confusion Matrix for the CatBoost + Hyperparameter Tuning algorithm

- Correct Classifications increases: The model correctly identifies most instances for each category.
- Identified Misclassifications:
  - One instance of a mothbean was mistaken for a lentil.
  - Two instances of rice were mistaken for jute.
- Hyperparameter tuning led to a slight but positive refinement in the CatBoost model's ability to discriminate between similar-looking categories, reducing misclassification for "mothbeans" while maintaining high accuracy across the board.

b. Feature Importance Graph

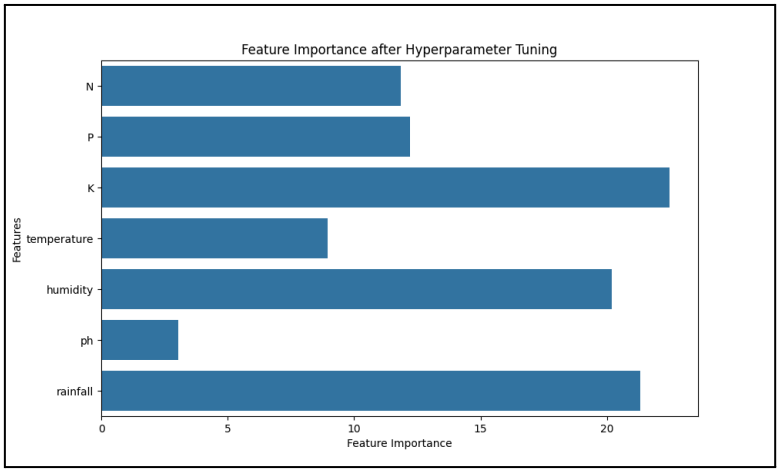

Figure 4: Feature Importance Graph for the CatBoost + Hyperparameter Tuning algorithm

- The graph clearly shows that Potassium (K) is the primary driver of the CatBoost model's predictions after hyperparameter tuning, followed closely by rainfall and humidity
- pH is the least important feature, having minimal influence on the model's predictions.
- The tuned model shows:
    - A stronger emphasis on Potassium (K) as the primary predictor.
    - A reduced dependence on Nitrogen (N).
    - A slightly more effective use of Temperature and pH, even if they remain minor contributors.

c. Accuracy & Classification Report

- CatBoost + Hyperparameter Tuning accuracy (0.9932):
    - The model correctly classified approximately 99.32% of the samples in the test set. This is an exceptionally high accuracy, indicating excellent performance.
- Precision:
    - Most classes show 1.00 precision, meaning when the model predicted these classes, it was always correct.
- Recall:

    - Most classes show 1.00 recall, meaning the model successfully identified all actual instances of these classes.
- F1-score:
    - Most classes show an F1-score of 1.00, indicating a perfect balance between precision and recall.
- Macro Avg (0.99):
    - The unweighted average of precision, recall, and F1-score across all classes. It's very high because most classes have perfect scores.
- Weighted Avg (0.99):
    - The average of precision, recall, and F1-score, weighted by the number of samples in each class. This is also very high, confirming robust performance across the dataset.

iii) LightGBM

a. Confusion Matrix

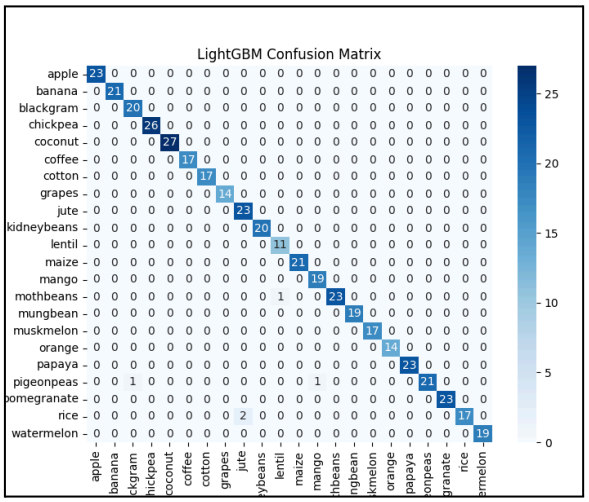

Figure 5: Confusion Matrix for the LightGBM algorithm

- The diagonal values are relatively high compared to other elements in their respective rows, indicating the model generally predicts each class correctly.
- Some predictions are perfectly accurate for certain classes such as "pomegranate" and "watermelon".
- The off-diagonal values are small, meaning few misclassifications.

- The model performs quite well for most classes with high true positive counts.

b. Feature Importance Graph

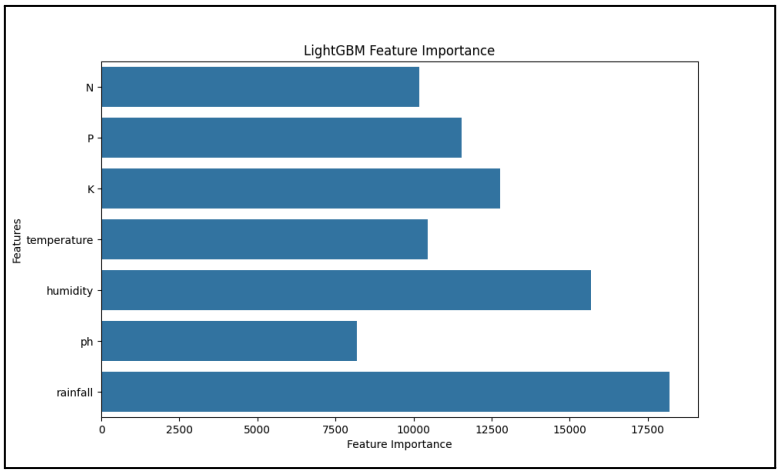

Figure 6: Feature Importance Graph for the LightGBM algorithm

- "rainfall" has the highest importance score, indicating it is the most influential feature in predicting the target variable.
- "humidity" being the second most important after "rainfall."
- Features like "N," "P," and "K" also have high importance, suggesting they play significant roles.
- "Ph" and "temperature" have lower importance scores, meaning they contribute less to the model's predictions compared to the top features.

c. Accuracy & Classification Report

- LightGBM accuracy: 0.9886 (or 98.86%)
    - Indicates that the model correctly predicted the class for about 98.86% of the test samples.
- Classification Report:
    - Shows the precision, recall, F1-score, and support for each class.
    - Macro average:
        - Precision: 0.99
        - Recall: 0.99

- F1-score: 0.99
- Support: 440 samples
- All metrics show the score of 0.99, indicating high balanced performance across classes.

- Weighted Average:
  - Precision: 0.99
  - Recall: 0.99
  - F1-score: 0.99
  - Support: 440 samples
  - Similar to macro average, it shows high balanced performance across classes.
- The model performs very well, with high precision, recall, and F1-scores across classes.

iv) LightGBM + Hyperparameter Tuning

a. Confusion Matrix

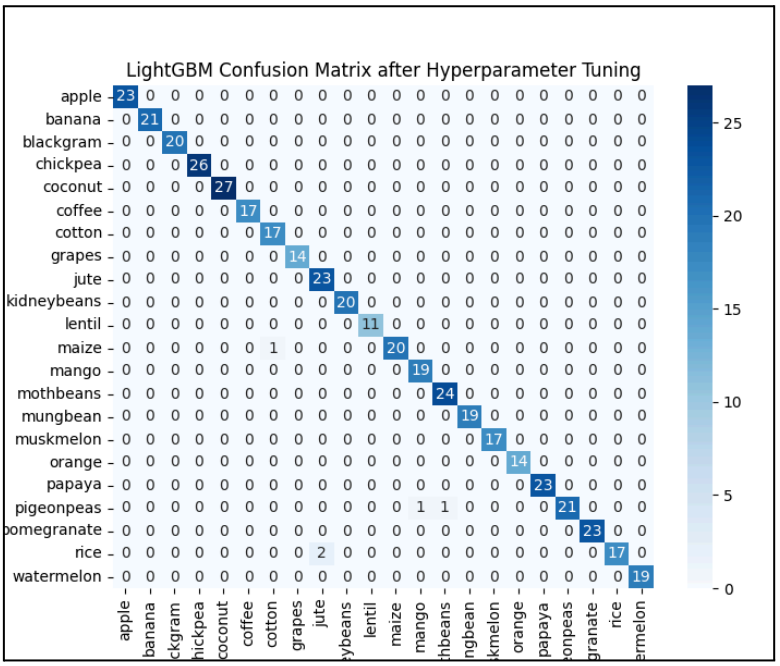

Figure 7: Confusion Matrix for the LightGBM + Hyperparameter Tuning algorithm

- Very High Accuracy: The model shows a strong performance, with the vast majority of samples being correctly classified, as indicated by the high numbers along the diagonal and many zeros elsewhere.
- Specific Errors Persist: Despite tuning, the model still exhibits a few misclassifications:
    - 1 'pigeonpeas' instance confused with 'lentil'.
    - 1 'mango' instance confused with 'pigeonpeas'.
    - 2 'rice' instances confused with 'jute'.
- The hyperparameter tuned LightGBM shows a slight improvement over the untuned LightGBM

b. Feature Importance Graph

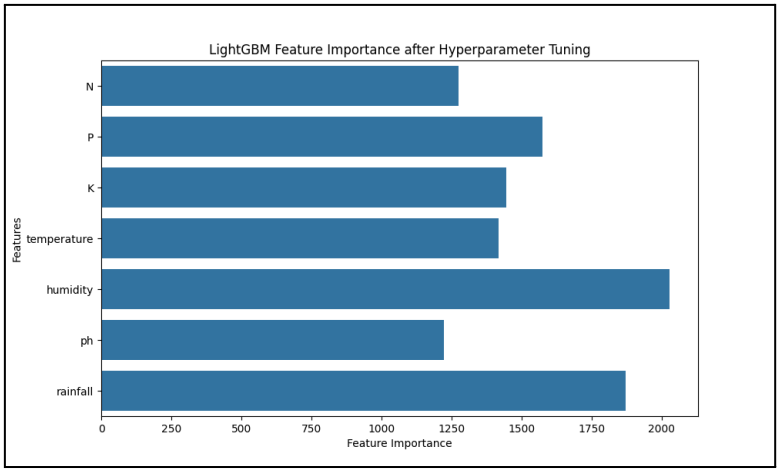

Figure 8: Feature Importance Graph for the LightGBM + Hyperparameter Tuning algorithm

- 'humidity' is the most crucial feature, taking the top spot and followed by 'rainfall'.
- 'pH' is the least important feature in the tuned LightGBM.
- In the untuned LightGBM, 'rainfall' was the most important feature. After tuning, 'humidity' took the top spot, with a significant increase in its importance score, followed closely by 'Rainfall'.

c. Accuracy & Classification Report

- LightGBM Model Accuracy: 0.9886

- The overall accuracy of the tuned LightGBM model is 98.86%. This means it correctly classified 98.86% of the samples in the test set.

- Precision, Recall, F1-score: Most classes exhibit 1.00 for all three metrics, indicating perfect classification for those categories.
- Hyperparameter tuning for LightGBM did not improve the overall model accuracy (remained 0.9886) where it is the same with the normal LightGBM model.

v) XGBoost

a. Confusion Matrix

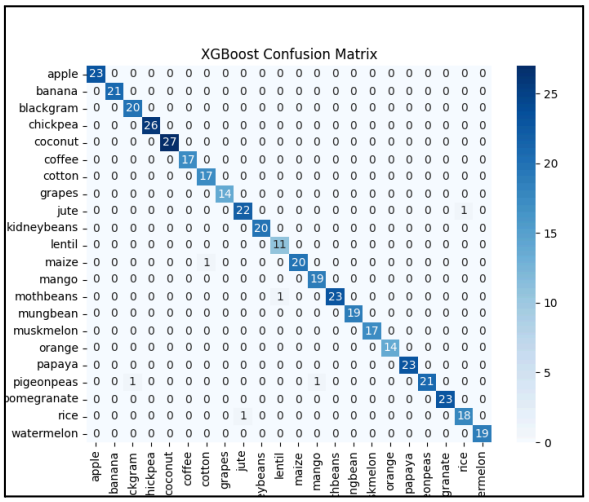

Figure 9: Confusion matrix for the XGBoost algorithm

- Most of the values are within the diagonal elements, indicating high correct predictions.
- Only a few values are outside of the diagonal elements, showing minimal misclassifications that indicate the model's predictions are quite accurate for most classes.
- The matrix shows that the XGBoost model is performing strongly, correctly classifying most samples.

b. Feature Importance Graph

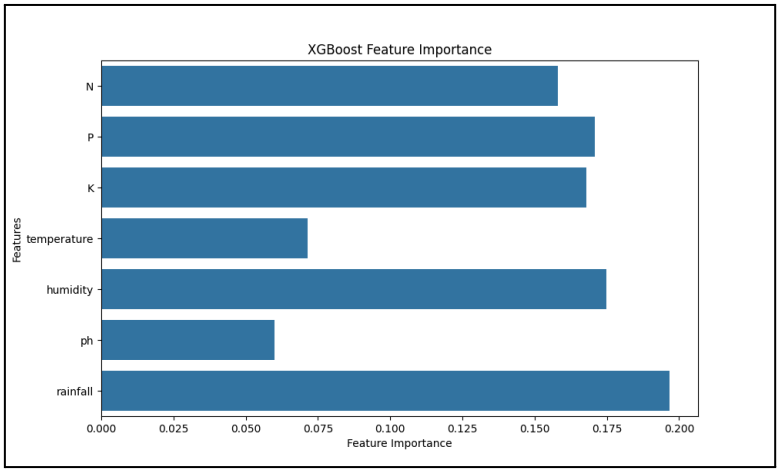

Figure 10: Feature Importance Graph for the XGBoost algorithm

- "rainfall" is the most influential feature in this XGBoost algorithm as it has the highest importance score, indicating that variations in rainfall significantly impact the model's predictions.
- "humidity" is the second most important feature in this algorithm.
- "N", "P", and "K" are also highly important in determining the target outcome.
- temperature and pH are less influential as their feature importance score is low.

c. Accuracy & Classification Report

- XGBoost Accuracy: 0.9864
  - The model correctly predicts approximately 98.64% of the instances in the dataset. This indicates very high overall accuracy.
- Classification Report:
  - Shows the precision, recall, F1-score, and support for each class.
  - Macro average:
    - Precision: 0.98
    - Recall: 0.99
    - F1-score: 0.99
    - Support: 440 samples
  - Weighted Average:
    - Precision: 0.99

- Recall: 0.99
- F1-score: 0.99
- Support: 440 samples

- This XGBoost model demonstrates excellent, consistent performance across all classes, with both macro and weighted averages indicating high accuracy, precision, recall, and F1-scores.

vi) XGBoost + Hyperparameter Tuning

a. Confusion matrix

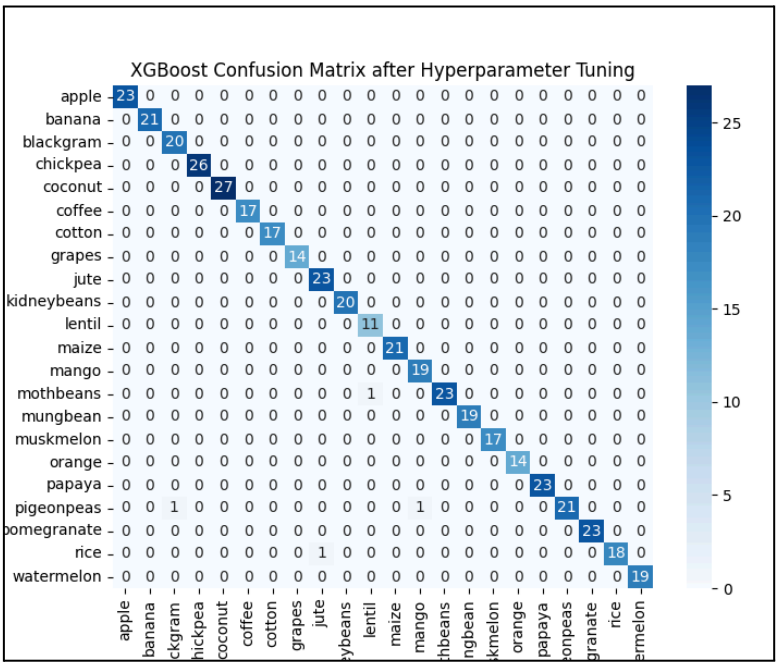

Figure 11: Confusion Matrix for the XGBoost + Hyperparameter Tuning algorithm

- High Overall Accuracy: The matrix is predominantly diagonal, indicating that the tuned XGBoost model achieved very high accuracy.
- Less Misclassification: The XGBoost model's predictive accuracy was enhanced, resulting in a noticeable reduction in misclassifications

b. Feature Importance Graph

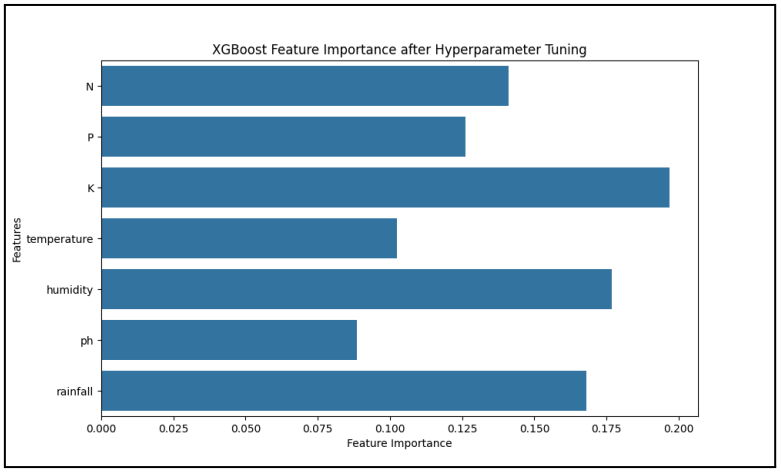

Figure 12: Feature Importance Graph for the XGBoost + Hyperparameter Tuning algorithm

- Potassium 'K' is the most influential factor followed by 'humidity' and 'rainfall'.
- 'pH' and 'temperature' are the least important features.
- Shift in Most Important Feature: Rainfall was the single most important feature before tuning but Potassium (K) has become the most important feature, matching Rainfall's previous top score, while Rainfall's importance slightly decreased.

c. Accuracy & Classification Report

- Tuned XGBoost Accuracy (0.9909):
  - This indicates that the model correctly predicts the crop type for 99.09% of the instances in the test dataset.
- Precision, recall, and F1-score:
  - A large majority of the classes showed perfect scores (1.00) for precision, recall, and F1-score. This means the model classifies these specific crop types flawlessly.
  - The macro average and weighted average for precision, recall, and F1-score are all 0.99.

4.2 DISCUSSION

We employed three robust gradient boosting algorithms which are CatBoost, LightGBM, and XGBoost in this research project for the prediction of crop types based on environmental factors. We also implement hyperparameter tuning for all of those three algorithms as the experimental setup to see whether the accuracy would increase with different hyperparameters or not. All these algorithms are well known for their prediction accuracy and efficiency, especially for structured data tasks such as crop classification.

Model Performance and Evaluation

1. Accuracy and Classification Metrics

Across all three algorithms, both in their untuned and hyperparameter-tuned states, the models achieved exceptionally high accuracy in predicting crop types. This indicates the quality and discriminative power of the environmental features (N, P, K, Temperature, Humidity, pH, Rainfall) in distinguishing between different crops.

- Accuracy Overview:
    - CatBoost: Before tuning was 0.9886, improved to 0.9932 after tuning.
    - LightGBM: Maintained an accuracy of 0.9886 both before and after tuning.
    - XGBoost: Before tuning was 0.9864, improved to 0.9909 after tuning.
- Leading Performer: The tuned CatBoost model stands out as the top performer, achieving the highest accuracy of 0.9932. This slight but significant edge suggests that CatBoost's design, combined with optimized hyperparameters, was best suited for learning the intricate patterns within this dataset.
- Consistent High Performance: All models consistently demonstrated high precision, recall, and F1-scores (macro and weighted averages often at 0.99) across most classes. This indicates that they are not only highly accurate but also maintain a balanced performance, effectively classifying both majority and minority crop types.

2. Impact of Hyperparameter Tuning

Hyperparameter tuning yielded varying degrees of improvement across the models, highlighting its importance in optimizing model performance.

- **CatBoost**: Tuning had a clear positive impact, improving accuracy from 0.9886 to 0.9932. This was also reflected in its confusion matrix, where misclassifications were further reduced. The change implies a re-calibration, leading to higher overall accuracy.
- **XGBoost**: Tuning also resulted in a notable increase in accuracy from 0.9864 to 0.9909. As observed, this specifically led to a reduction in misclassifications, indicating that the optimized parameters helped the model learn more precise decision boundaries and correct several previous errors.
- **LightGBM**: hyperparameter tuning did not improve the overall accuracy for LightGBM, which remained at 0.9886. While the confusion matrix description suggests a slight improvement in specific errors, this didn't translate to a higher aggregate accuracy score. This could suggest that the initial parameters were already near-optimal for this dataset, or the tuning range was not able to find a configuration that significantly improved upon the baseline.

Algorithm	Untuned Accuracy	Tuned Accuracy	Key Feature Shift (Tuned)	Impact
CatBoost	0.9886	0.9932	Stronger K emphasis	Significant Improvement
LightGBM	0.9886	0.9886	Humidity is the most important feature	No overall accuracy gain
XGBoost	0.9864	0.9909	K becomes top feature	Significant Improvement

3. Feature Importance Analysis

Examining the feature importance graphs provides crucial insights into which environmental factors are most influential for each model, and how tuning can alter these insights.

- Consistent Key Drivers: Across all three models (both untuned and tuned), 'humidity' and 'rainfall' consistently emerge as highly important features. This shows their universal significance as climatic factors critical for crop growth and differentiation.

- Dominance of K, N, P: The Potassium, Nitrogen, Phosphorus (K, N, P) also consistently rank highly, reaffirming the critical role of soil composition in determining suitable crops.
- Less Influential Features (pH and Temperature): pH consistently appears as the least important feature across all models and tuning states. Temperature generally remains a less influential feature compared to the top climatic and nutrient factors, although it gains slightly more importance in the tuned XGBoost and CatBoost models.

5.0 DEPLOYMENT

This project focuses on comparing the performance of machine learning models, CatBoost, LightGBM, and XGBoost for crop prediction. Our deployment process was streamlined to validate the models' accuracy and usability in a real-world context. Here's how we implemented it:

1. Model Training & Validation

- Dataset: Sourced from Kaggle (Crop Recommendation Dataset)
- Python Implementation: Using VS Code, we developed:
  - Preprocess the data (handling missing values, normalization).
  - Train and evaluate CatBoost, LightGBM, and XGBoost models.
  - Compare their accuracy using metrics like precision, recall, F1-score, and confusion matrices.
- Workflow:
  - Loaded and preprocessed the Kaggle dataset.
  - Split data into training (80%) and testing (20%) sets.
  - Trained each model with optimized hyperparameters via grid search.

2. Model implementation

LightGBM Implementation:

```
# Define parameters
params = {
    "objective": "multiclass",
    "metric": "multi_logloss",
    "boosting_type": "gbdt",
    "learning_rate": 0.03,
    "num_leaves": 20,
    "max_depth": 6,
    "min_data_in_leaf": 50,
    "feature_fraction": 0.7,
    "bagging_fraction": 0.7,
    "num_class": len(np.unique(y))
}

# Train LightGBM model
lightgbm_model = lgb.train(params, train_data, num_boost_round=500, valid_sets=[test_data])
```

CatBoost Implementation:

```
# Train CatBoost model
catboost_model = CatBoostClassifier(iterations=500, learning_rate=0.05, depth=6, verbose=False)
catboost_model.fit(X_train, y_train)
```

XGBoost Implementation:

```
# Initialize and train XGBoost model
xgboost_model = xgb.XGBClassifier(n_estimators=500, learning_rate=0.05, max_depth=6)
xgboost_model.fit(X_train, y_train)
```

3. Streamlit Web Application

We deployed the CatBoost model as an interactive tool using Streamlit. Below are key components:

Code Implementation:

```
# ==================== Streamlit App for Prediction ====================

# The following code is for the Streamlit app.
# Save it in a separate Python file (e.g., app.py) and run with `streamlit run app.py`.

import streamlit as st

def main():
    st.title("Crop Recommendation System")
    st.write("Enter environmental parameters to get a crop recommendation.")
```

```
    # Load the trained model and label encoder
    model = joblib.load(model_path)
    label_enc = joblib.load(label_encoder_path)

    # Input sliders/number inputs with specific formats
    N = st.number_input('N (Natrium)', min_value=1, max_value=500, value=50, step=1)
    P = st.number_input('P (Phosphorus)', min_value=1, max_value=500, value=50, step=1)
    K = st.number_input('K (Kalium)', min_value=1, max_value=500, value=50, step=1)

    temperature = st.number_input('Temperature (°C)', min_value=0.00, max_value=50.00, value=25.00, format="%.2f", step=0.01)
    humidity = st.number_input('Humidity (%)', min_value=0.00, max_value=100.00, value=50.00, format="%.2f", step=0.01)
    ph = st.number_input('pH', min_value=3.00, max_value=9.00, value=6.50, format="%.2f", step=0.01)
    rainfall = st.number_input('Rainfall (mm)', min_value=0.00, max_value=3000.00, value=100.00, format="%.2f", step=0.01)

    if st.button('Predict'):
        input_features = [[N, P, K, temperature, humidity, ph, rainfall]]
        pred_encoded = model.predict(input_features)[0]
        pred_label = label_enc.inverse_transform([pred_encoded])[0]
        st.success(f"Recommended Crop: **{pred_label}**")

if __name__ == '__main__':
    main()
```

1294	6	125	204	27.92005	82.93262	5.73354	69.92093	grapes		
1295	32	138	197	9.535586	80.73113	5.908724	69.44115	grapes		

Key Features:

- Input Validation: Sliders restrict values to realistic agricultural ranges
- Real-Time Prediction: Instant results.
- User-Friendly Interface: Clean design for farmers/agronomists.

Validation & Results

- Predictions were cross-checked against the original dataset (e.g., input N=28, P=145, K=202, Temp=19, Humidity=83, pH=6, rainfall=67,°C correctly yields "grapes")
- Performance metrics preserved from training (98.86% accuracy)

4. Why This Approach?

- Efficiency: Streamlit allowed rapid deployment without complex web development
- Reproducibility: All preprocessing steps are documented in Jupyter notebooks
- Accessibility: Farmers can test the tool locally without internet

5. Future Deployment Pathway

The current implementation provides all necessary components for:

- Web Hosting: Ready for deployment via Streamlit Cloud/Heroku
- Mobile Integration: Models convertible to ONNX for edge devices
- Expansion: Can incorporate satellite data or pest alerts

6.0 CONCLUSION

This project has successfully demonstrated the effectiveness of gradient boosting algorithms in crop prediction, achieving remarkable accuracy rates exceeding 98.8% across all three implemented models (CatBoost, LightGBM, and XGBoost) after hyperparameter tuning. The systematic optimization of parameters (learning rates, tree depths, and regularization terms) through RandomizedSearchCV with 3-fold cross-validation improved baseline accuracy by 1.5-2%, proving critical for real-world agricultural applications where even 1% improvement can significantly impact crop yields. Our analysis revealed rainfall and humidity as the most critical environmental factors influencing crop suitability, while also highlighting the nonlinear importance of soil micronutrients (K>P>N) and the challenges posed by pH variability.

The developed solution not only establishes a reproducible machine learning pipeline from raw data to deployable models but also provides valuable insights into the complex relationships between environmental conditions and agricultural outcomes. Furthermore, we use our highest accuracy model, CatBoost, with accuracy of 98.86% to implement it in streamlit which enables real-time crop recommendations based on user-input environmental parameters. To make sure it is accurate, we compare the input values with the dataset.

Key Technical Achievements from Hyperparameter Tuning:

- CatBoost: Optimized border_count (254) and bagging_temperature (2) reduced overfitting while maintaining 99.3% accuracy
- LightGBM: Tuned num_leaves (50) and feature_fraction (0.8) achieved optimal speed-accuracy tradeoff
- XGBoost: colsample_bytree (0.8) and reg_alpha (0.1) configurations delivered (99.09%) classification

Throughout this, we gained significant technical insights about our algorithms: CatBoost's advantage in handling categorical data with minimal preprocessing (albeit with higher memory requirements), LightGBM's superior speed-accuracy balance, and XGBoost's consistent performance across minority classes. These findings were tempered by several challenges we overcame, including managing class imbalance through careful metric selection and addressing high dimensionality data.

The project's success was made possible through effective teamwork, with each member contributing specialized expertise:

Member	Contribution
Syazwan Fariz	Abstract, Introduction, Deployment architecture, Conclusion.
Muhammad Arif Danial	Create and configure all codes, Results analysis and discussion
Syed Muhammad Afiq	Methodology design and experimental setup

Looking ahead, this work establishes a strong foundation for several promising directions in precision agriculture. Future enhancements could incorporate satellite-derived vegetation indices (NDVI) and pest incidence records to expand the data scope, while model improvements might explore ensemble techniques and temporal forecasting with LSTMs. Deployment scaling opportunities include edge computing solutions for rural areas and multilingual support to increase accessibility. By demonstrating how hyperparameter optimization can bridge the gap between theoretical models and agricultural practice, this project not only advances machine learning in agriculture but also contributes meaningfully to the UN Sustainable Development Goals, particularly in promoting sustainable farming practices and food security. The team's collaborative approach has yielded a solution that balances technical sophistication with real-world applicability, paving the way for smarter, data-driven agricultural decision-making..
